(54) **Card edge power distribution system.**

(57) A system for distributing electrical power to side edges (108,112) of a daughter card (102) upon insertion into a card cage (10) includes a pair of source and return bus bars mounted on at least one of the side edges and electrically connected by arrays of terminals (172) to power circuits of the card, insulated by a cover having a rail (126) for following the guide channels (18,20) of the card cage (10) at each card location. Rearward ends of the bus bars have blades (122,124) which are received into receptacle contacts mounted in the card cage (1) above and below the backplane (14), which are mounted at each card location and electrically connected to source and return busses of the card cage. The receptacle contacts are float mounted to be easily incrementally moved upon blade receipt during card module (100) insertion, and also easily incrementally moved after blade mating when power connections are established, to then permit precision adjustment of rear card edge (104) in two dimensions so that card edge connectors (106) thereon become aligned with corresponding backplane connectors (16) for subsequent high density signal terminal mating.

EP 0 465 013 A1

The present invention relates to the field of electrical connection systems and more particularly to the distribution of electrical power in card cage assemblies.

Card cages are known which comprise a framework within which a plurality of circuit panels or daughter cards are insertable, and within which is disposed a backplane transverse to the back edges of the daughter cards. The upper and lower daughter card edges conventionally are disposed within upper and lower channels defined by the card cage framework and extending to selected positions along the backplane to define the card position within the card cage and to guide the card during insertion into and removal from the card cage. Electrical circuitry of the cards is connected to electrical circuitry of the backplane by any of several types of known connectors and terminals, and is thereby interconnected by the backplane to circuitry of other cards of the array and to other electrical components on the opposite side of the backplane.

Typically each daughter card in present commercial card cages receives all necessary power for its components from the backplane through a plurality of terminals. One typical method involves providing a multilayer backplane having power-carrying circuit paths embedded within it, involving significant fabrication expense, to which terminals are engaged to transmit the power at current levels, ordinarily of about one ampere per terminal, through connectors to the daughter card. Connectors which must house the quite numerous power-carrying terminals also must house signal terminals for the primary purpose of providing signal transmission to and from the daughter cards; signal terminals are thus limited in number and in their position, which in turn limits the capabilities of the daughter cards. Also, the current levels presently available limit the number and types of components usable with the daughter cards.

One approach to distribute power to daughter cards in an improved manner is disclosed in U. S. Patent No. 4,846,699 in which the power is provided to upper and/or lower edges of each daughter card rather than along the back edge. The upper and/or lower guide channels are defined by elongate electrical connectors containing a plurality of electrical terminals which are movable into and out of engagement with corresponding contact locations along the card by an actuation system within each connector. The plurality of terminals thus distributes electrical power to discrete locations and discrete power circuits on the card. Thus during card insertion and removal the contact sections of the terminals are retracted from the guide channel and would not engage any portions of the card nor interfere with insertion and removal of a

card; only when the cards have been fully inserted and locked into position are the terminals moved into electrical engagement with the contact means along the card edge. Examples of such zero insertion force connectors are particularly disclosed in U. S. Patent No. 4,789,352 and No. 4,834,665. With such connectors, conductors such as flat cables are needed to be routed through the card cage framework above and below the daughter cards and electrically connected to the terminals of the connectors and to a power supply for the card cage.

It is desired to provide a power distribution system for daughter cards of a card cage which utilizes a portion other than the back edge of each card for transmitting power to the card, without interfering with insertion or removal of the card.

It is desired to provide such a system which minimizes the amount of daughter card real estate utilized for receipt and return of power while retaining the benefits attained by a substantial plurality of power connecting sites.

It is additionally desired to provide a power distribution system which electrically connects with the card upon insertion and disconnects upon card withdrawal.

It is also desired to provide such a system which does not require a plurality of cables routed throughout the card cage.

It is further desired to provide such a system which would provide power to each card at substantially increased levels without significant voltage drop.

It is further desired that such a power distribution system not obstruct forced air flow between adjacent daughter cards in the card cage, needed for cooling.

The power distribution system of the present invention includes a pair of bus bars mounted to at least one of the upper and lower edges of a daughter card, with an insulator thereover. Each bus bar includes flange portions coextending inwardly along the corresponding card edge and includes a plurality of contact terminals secured to the bus bar and extending into plated through-holes into the card for electrical connection to power circuitry of the card. At the rearward ends of the bus bars are blade-shaped contact sections extending further rearwardly beyond the card's rear edge. Mounted to the framework at the rear of the card cage are upper and/or lower assemblies of pairs of receptacle contacts at each daughter card location and electrically connected to a power bussing system of the card cage having source and return paths, the receptacle contacts of each pair being associated with each bus bar of a daughter card to be inserted and matable with the blade-shaped contact section of the respective bus bar and comprising a

separable interface. One of each pair of bus bars may be a source path and the other a return path, and preferably the blade-shaped contact section of the return path bus bar is longer to engage its respective receptacle contact first during card insertion and disengage last upon card withdrawal.

According to one aspect of the invention, the bus bars include elongate body sections having several flanges extending therefrom; the bus bars are of low resistance conductive metal and have a substantial mass because of their substantial current-carrying cross-section. The bus bars can be assembled together with insulation between their body sections, such that their flanges are laterally offset from the body sections and alternate with and are slightly spaced from each other along the bus bar length. Mounting of the bus bars to the card edge can be assuredly attained through the use of a plurality of compliant pin terminals which are firmly secured within holes through the bus bar flanges along the length of each bus bar and also firmly secured within corresponding through-holes along the card edge, and preferably are of the type having a pair of compliant sections as disclosed in U. S. Patent No. 4,186,982. The compliant pin terminals also establish the substantial plurality of electrical connections to the card power-carrying circuitry along the card edge, for transmitting power to a substantial plurality of card sites considered necessary for effective power distribution. The bus bars may have several flange sections alternating with the flange sections of the other bus bar and having their card-proximate surfaces in a common plane to face a common surface of the card, and the compliant pin terminals may coextend in two rows into the card from a common side, facilitating assembly. The compliant pin terminals being disposed in two spaced rows significantly resists damage to the card from torque resulting from lateral stress on the bus bars.

In another aspect of the invention, the receptacle contacts are of the type disclosed in U. S. Patent No. 4,845,589 and include a receptacle contact section including a lead-in defining a capture range for matingly receiving thereinto a blade-shaped bus bar contact section, which has been substantially aligned therewith by guides of the card cage followed by rails of the daughter cards during card insertion. Each has a plurality of opposed spring arms of substantial spring strength establishing a contact normal force of about four pounds per spring arm, required to establish assured low resistance electrical connections for the transmission of power, for instance at 75 amperes.

Since the card edge connectors along the back edge of the card contain a substantial plurality of signal terminals small in size and closely spaced, it is crucial that the connectors which house them are

precisely aligned with the mating connectors mounted to the backplane at least just before the signal terminals matingly engage. Alignment posts of the backplane connectors can enter post-receiving holes of the card edge connectors in order to incrementally adjust the position of the card edge connectors, provided that the power distribution system does not interfere with the incremental adjustment movement of the card's rear edge to conform the position of the card edge connectors to the backplane connector alignment posts. The effect of the substantial mechanical gripping of the blade-shaped sections by the receptacle contacts on the card edge adjustment, is minimized by mounting the receptacle contacts in a manner permitting floating thereof with little mechanical resistance of the type which would otherwise occur were the receptacle contacts to be rigidly mounted and the stiff spring arms to be even further deflected.

The receptacle contacts used with the present invention are loosely mounted along a shaft secured within a castellated clevis block permitting rotation therearound in a vertical plane parallel to a daughter card. Each receptacle contact is mounted in a loose fit between clevis block which combined with a loose fit with respect to the shaft permit float in two orthogonal dimensions to a limited extent sufficient to accommodate all adjustment movement of the card edge. Each receptacle contact may be assuredly connected to the power bussing system of the card cage by a corresponding rearward receptacle contact section gripping a respective blade-shaped section of the source or return card cage bussing means with substantial contact normal force, which provides the location about which the receptacle contact pivots when moved incrementally by the blade-shaped contact section of the source or return bus bar upon initial engagement during card insertion, and then incrementally by the card edge alignment system. Thus the assembly of receptacle contacts to the clevis block provides a floating separable interface, with the respective receptacle contacts permitted to move in two orthogonal directions (which define a plane parallel to the backplane) independently of each other while still gripping in the third or axial dimension the opposed blade-shaped contact sections of the card cage bussing system and the bus bars of the daughter cards. Thus the incremental adjustment movement essentially does not encounter resistance from needing to deflect the stiff spring arms of the receptacle contacts nor friction resistance from needing to move the blades along the arrays of opposed spring arms gripping them.

It is an objective of the present invention to provide a system for distributing electrical power to a substantial plurality of sites along the upper

and/or lower edge of a daughter card, electrically connectable with bussing means of the card cage upon card insertion.

It is also an objective for the power connections of the system be matable and separable automatically during card insertion and withdrawal.

It is also an objective that such a power distribution system engage prior to signal connections being established between the daughter card and the backplane, and further that the return power circuit be established prior to the source power circuit.

It is additionally an objective that the two electrical connections already established during the intermediate stage of card insertion, each sufficient for transmitting 75 amperes, not interfere with the incremental adjustment in card edge position necessary at the final stage of daughter card insertion to precisely align the multitude of signal terminals in the high density card edge connectors with corresponding terminals of the back plane connectors.

It is a further objective that the bus bars of substantial mass be secured and electrically connected to a respective card edge in an assured manner and in a manner which minimizes the effects of torque on the card edge without necessitating mounting hardware nor heat, flux, solder nor adhesives in order to simplify card fabrication and assembly of the bus bars to the card edge.

It is an additional further objective that the bus bar assemblies for daughter cards be essentially independent of variations in card thickness in a large range of possible thicknesses, such as between 0.085 and 0.25 inches.

It is also a general objective that the power distribution system of the present invention minimize the voltage drop through all the electrical connections between the cage bussing system and the daughter card power circuits.

It is additionally an objective that the power distribution system and especially the bus bar assemblies not obstruct forced air flow between the daughter cards for cooling purposes.

An example of an embodiment of the present invention will now be described by way of example with reference to the accompanying drawings, in which.

FIGURE 1 is an isometric view of a card cage having a backplane and locations for a plurality of daughter cards, and a daughter card for insertion therein, having the power bussing system of the present invention;

FIGURE 2 is an isometric view of a card in position in its guide channels of the card cage of Figure 1 showing the power distribution system; FIGURE 3 is an enlarged portion of two card modules in the card cage of Figures 1 and 2

showing the separable interface of the power distribution system, with blade contact sections of the buses of a card module associated with float-mounted receptacle contact members of the card cage bussing system, and showing a card edge connector along the rear edge of a card module and an associated backplane connector;

FIGURES 4, 5, and 6 are diagrammatic illustrations of an upper edge of a card module having a bus bar assembly mounted therealong, in several phases of insertion into a card cage and showing mating of the bus bar contact sections occurring prior to mating of the card and backplane connectors, with an alignment system shown;

FIGURES 7, 8 and 9 show a bus bar assembly for a card edge, prior to assembly and fully assembled to be mounted onto a card edge, with Figure 9 being an enlarged view of a portion of a bus assembly showing an insulator retained over the bus bar pair;

FIGURE 10 is an enlarged view of a flange of a bus bar with strips of compliant pin terminals to be mounted thereinto;

FIGURE 11 is a representative section view of a portion of a card module edge having a bus bar assembly mounted therealong, showing several compliant pin terminals mechanically securing and electrically connecting the bus bar to the card;

FIGURE 12 is an isometric view of a clevis block and representative receptacle contact therefore prior to assembly together, and showing the mounting shaft and a bushing;

FIGURE 13 shows the receptacle contact block fully assembled and also showing the associated power bussing system of the card cage to which it will be connected upon mounting in the card cage;

FIGURES 14 to 17 are diagrammatic illustrations in plan view of a bus bar assembly of a card module during a mating sequence, showing the floating nature of the receptacle contacts of the block of Figure 13 in response to the first blade and the second blade in Figures 14 and 15, the engagement of the alignment system of the card edge and backplane connectors in Figure 16, and the card fully inserted and fully connected in Figure 17.

A card cage 10 as in Figures 1 and 2 includes a framework 12, a backplane 14 on which are mounted a plurality of vertically disposed high density backplane connectors 16 corresponding to daughter card locations, and a plurality of pairs of upper and lower guide channels 18,20 defined in guide members 22,24 extending forwardly from backplane connectors 16 at the card locations to

leading ends 26,28 at front face 30 of the cage 10. A representative daughter card module 100 includes a daughter card 102 having an inner or rear edge 104 on which is mounted a single high density card edge connector 106 (or series of connectors). Along upper edge 108 of card module 100 of Figure 1 is mounted a bus bar assembly 110, and along lower edge 112 is mounted a similar bus bar assembly 114. Each bus bar assembly includes a pair of first and second bus bars 116,118 (see Figures 5 and 6) covered by an insulator 120. At rearward ends of bus bar assemblies 110,114 are first and second blade-shaped contact sections 122,124 of the first and second bus bars 116,118 which extend outwardly from insulator 120 and rearwardly of rear card edge 104 and card edge connector 106.

Insulator 120 of each bus bar assembly 110,114 includes a rail 126 to follow guide channels 18,20 during card insertion. To assure that the card module is appropriately oriented, polarization may be provided by the depth of upper guide channel 18 being greater toward one side at 19 and the depth of lower guide channel 20 being greater toward the same side at 21; correspondingly the upper rail 126 would then include an offset narrow flange portion 128 toward that side after appropriate mounting and the offset narrow flange portion 128 of the lower rail would be positioned toward that same side after appropriate mounting so that the narrow rail flange portions 128 would prevent a daughter card module 100 being inserted in the improper inverted orientation wherein the rail flange portions would occur on the opposite side of the guide channels from the side of deeper channel portions 19,21. Other configurations of complementary rail/channel engagement geometries are possible, where the cross-section geometries of the upper and lower rail/channel systems are asymmetric between left and right sides to assure proper orientation of the daughter card during insertion; it is preferred that the geometries required of the upper and lower insulators (and likewise the upper and lower guide members) be mirror image opposites in cross-section so as to permit manufacture thereof by a common extrusion, and then be mountable in opposed orientations.

Card module 100 includes mounted pivotably along front edge 130 an insertion/ejection member 132 at the forward end of upper edge 108 and another such insertion/ejection member 134 at the forward end of lower edge 112, each of which includes a catch-receiving slot 136 cooperable with respective catches 32,34 of the card cage framework 12 to assist final stages of card module insertion. Insertion/ejection members 132,134 are mounted to daughter card 102 by pivot pins 144 extend-

ing through apertures of the card and through both tines of apertured clevises 146. Insertion/ejection members 132,134 are provided with elongate handles 138 movable flush to the daughter card forward edge 130; members 132,134 assist completion of card module insertion by providing mechanical advantage to overcome the resistance to bus bar and connector mating, and to retain the card module in position and also to initiate first stages of card module disengagement during withdrawal and removal. Catches 32,34 may be rods mounted transversely through leading ends of guide members 22,24. Also shown within the card cage 10 are upper and lower power bus assemblies 36,38, and forwardly thereof are receptacle contact blocks 40,42.

Figure 2 illustrates card module 100 in a fully inserted position within card cage 10, showing both bus bar assemblies 110,114 in mated engagement with respective pairs of receptacle contacts 44,46 of upper and lower receptacle contact blocks 40,42. Blade contact sections 116,118 have been received into receptacle contact sections 48,50 (Figure 3) of receptacle contacts 44,46 each having a plurality of spring arms 52 opposed in pairs, the spring arms 52 having substantial spring strength. The backplane 14 of the card cage has been removed to show all of the essential portions of the separable interface of the power distribution system of the present invention from the bus bar assembly to the card cage bussing system.

In Figure 3 is shown an enlargement of the lower separable power interface defined by the bus bar blade contact sections of lower bus bar assembly 114 and the receptacle contact sections 48,50 of contacts 44,46 mounted in lower block 42, with only blade contact section 122 of the return bus shown. The separable interface is mounted to framework 12 and disposed below the lower edge of backplane 14, and receptacle contact sections 48,50 extend forwardly of backplane 14 for early engagement with blade contact sections 122,124. Also shown is the rearward receptacle contact section 54 of a receptacle contact 44 mated with a blade-shaped contact section 56 of return bus member 58 of lower power bus assembly 38.

On backplane 14 is seen a lower portion of high density backplane connector 16 within which are secured a multitude of electrical signal contacts (not shown) which will mate with corresponding signal contacts (not shown) in card edge connector 106 mounted along rear edge 104 of daughter card 102. In order to assure that the plurality of mating signal contacts of the mating connectors will mate properly, an alignment system is provided comprising of for example several alignment posts 80 spaced along and solidly mounted to each backplane connector 16 and/or to backplane 14 and

precisely located with respect to the signal contacts of the connector. The alignment posts 80 cooperate with post-receiving apertures (Figures 14 to 17) of card edge connector 106 which apertures are similarly precisely located with respect to the card edge connector terminals. The engagement of the leading ends of alignment posts 80 with bearing surfaces of the aperture entrances (Figures 16 and 17) urges the card edge connector (and the card module to which it is affixed) to adjust its position to be precisely aligned with the backplane connector, which could involve incremental movement vertically or horizontally or both as the card module 100 continues to be urged forwardly into card cage 10 along upper and lower guide channels 18,20.

Referring now to Figures 4 to 6, the mating sequence of card module 100 into card cage 10 is depicted in diagrammatic form and shows the upper bus bar assembly 110 mating with the upper separable interface comprised of upper receptacle contact assembly 42 and upper bus assembly 36 of the card cage. Receptacle contact member 44 is shown including an insulative bushing 60 extending through body section 62 and mounted on shaft 64 of clevis block 66 in upper contact assembly 42. Upper bus assembly 36 includes return bus member 58 and source bus member 68, with an appropriate insulation layer 70 therebetween; rearward receptacle contact section 54 of contact member 44 is mated onto blade-shaped contact section 56 depending from contact member 72 affixed to return bus member 58 and extending forwardly therefrom. Blade-shaped contact sections 74 similarly depend from contact members 76 affixed to source bus member 68 (Figure 13) in each of upper and lower bus assemblies 36,38, arranged so that sections 74 extend upwardly to alternate with sections 56 extending downwardly to define a common row of blade-shaped contact sections for the array of rearward receptacle contact sections of contact assemblies 40,42.

In Figure 4 card module 100 has been inserted most of the way into card cage 10 with rail 126 guided within guide channel 18 of guide member 22, and insertion/retention member 132 is oriented about pivot pin 144 into position A for catch 32 to abut arcuate engagement surface 140 forwardly of slot 136. Also seen is an insulative end cover member 148 similarly mounted by pivot pin 144 insulating the ends of the bus bars. Blade-shaped contact section 122 of the return bus bar extends rearwardly toward forward receptacle contact section 48 of contact member 44 to be received between opposed pairs of spring arms 52. Shorter blade-shaped contact section 124 of source bus bar is shown in phantom behind blade-shaped contact section 122. Card edge connector 106 on rear

edge 104 of card 102 faces and is spaced from corresponding backplane connector 16 mounted on backplane 14, and one of the several alignment posts 80 for backplane connector 16 is shown extending forwardly theretowards.

In Figure 5 insertion/ejection member 132 has been lowered to position B so that tine 142 opposed from arcuate engagement surface 140 is raised along the inside surface of catch 32 and bearing thereagainst, thus urging card module 100 further inwardly. The leading blade edge of blade-shaped contact section 122 has entered the lead-in defined by the diverging spring arm free ends of spring arms 52 of forward receptacle contact section 48 and has deflected the spring arms of the opposing pairs apart and entered therebetween meeting and overcoming substantial resistance to mating. Second, shorter blade-shaped contact section 124 will shortly thereafter similarly mate with corresponding forward receptacle contact section 50 again meeting and overcoming substantial resistance to mating, as insertion/ejection member 132 is moved further toward front card edge 130. Alignment post 80 approaches card edge connector 106 to begin its precision alignment function.

In Figure 6 full card module insertion has been attained, with insertion/ejection member 132 in final position C along front card edge 130. The blade-shaped contact sections of both bus bars have been fully mated with respective receptacle contact sections. Alignment post 80 of backplane connector 16 has entered the corresponding aperture of card edge connector 106 and aligned the card edge connector with the backplane connector, and mating thereof has occurred with all pairs of mating terminals having been precisely aligned and mated.

Referring to Figures 7 to 10, the portions of bus bar assembly 110 for card module 100 are illustrated, and assembly thereof will now be described. Return bus bar 116 includes first blade-shaped contact section 122 extending therefrom, longer than second blade-shaped contact section 124 extending from source bus bar 118. Both contact sections 122,124 are offset a distance apart to mate with similarly spaced apart forward receptacle contact sections 48,50 of receptacle contact assembly 42 and include blade-like double beveled leading edges to facilitate mating therewith. Bus bars 116,118 are affixed together with a layer of insulative material 158 therebetween.

Bus bar 116 includes a plurality of flanges 150 alternating with recesses 152 and offset from the bus bar side surface toward bus bar 118 a distance equal to half a flange thickness plus half the thickness of insulative layer 158; bus bar 118 similarly includes a plurality of flanges 154 alternating with recesses 156 and offset toward bus bar 116. The flanges of each bus bar are located opposed from

respective ones of the recesses of the other bus bar, and all flanges and recesses are shaped and dimensioned so that when the bus bars are affixed together with a layer of insulation 158 therebetween, the flanges of both define a common row specifically to define substantially a common plane of card-facing surfaces 160,162. Side edges of each flange are spaced from opposing side edges of adjacent flanges a precise amount for electrical isolation at spacings 164 which may be about 0.045 inches wide sufficient for voltage levels of the 5 to 10 volt range commonly desired in card cage power applications. The embodiment shown includes four flanges each about 1 inch long; however the number of flanges and their length can be modified as desired.

In Figure 9 is shown one manner of retaining insulator 120 on a bus bar assembly: the flange-covering section 194 of the insulator is ultrasonically deformed at at least one spacing 164 between flanges 150 and 154 so that a portion 196 of the insulator material is now embedded therebetween preventing axial insulator movement. Another manner of insulator securement optionally could comprise or include insulative member 148 (Fig. 4) mounted to the daughter card at the front edge 130 at each insertion/ejection member 132,134 by the same pivot pin 144 by which the insertion/ejection member 132,134 is mounted. The corners of the insulator could be rounded if desired to facilitate forced air flow therearound.

In each flange 150,154 of both bus bars 116,118 are preferably two rows of pin-receiving apertures 166 to receive therein respective first compliant sections 170 of first sections 172 of pin terminals 174. Pin terminals 174 are preferably stamped and formed on carrier strips 176 and retained thereon during assembly and thereafter. As seen in Figure 11, carrier strips 176 extend integrally from central terminal sections 178 between first compliant sections 170 and second compliant sections 180 on second terminal sections 182. First compliant sections 172 are gripped within appropriately dimensioned apertures 166, thereby requiring at least about five pounds axial pushout force on each terminal for extraction. When bus bars 116,118 have each been fully loaded with compliant pin terminals 174, they are secured together so that second terminal sections 182 coextend outwardly from card-facing surfaces 160,162 of flanges 150,154.

Bus bar assembly 110 is applied to the reference surface side of card edge 108 by insertion of the plurality of second terminals sections 182 into respective through-holes 184 arrayed in two rows in each of alternating regions 186,188. Second compliant sections 180 are gripped by the wall surfaces of through-holes 184, thereby requiring at

least about five pounds axial pushout force on each terminal for extraction. Compliant sections 172,182 are preferably of the type disclosed in U. S. Patent 4,186,982 which can establish such substantial levels of force that assured mechanical and electrical connections are made by the terminals to the substrate without solder or any additional retention mechanism. Thus with a plurality for example of 92 terminals for each bus bar (23 per flange, in rows of 12 and 11 each), a total of 184 terminals having the specified type of compliant section is sufficient to establish that an aggregate force of at least about 900 pounds would be required to remove each of the bus bar assemblies 110,114. While such excellent retention force is defined by the particular compliant pin terminals disclosed, other mounting means such as bolts may be used for bus bar mounting if other types of terminals were to be used. Tooling and apparatus is in commercial use which can apply the necessary force of less than forty pounds per pin terminal, or in other words a maximum total of about 7500 pounds to apply each bus bar assembly to the daughter card.

In the embodiment shown, the carrier strips 176 define a selected spacing between the flanges and the card surface, and also serve to retain the terminals precisely spaced during assembly and to act as a stop mechanism to assure all pin terminals inserted to a common desired depth. The two-row array of terminals resists damage to the card edge from torque which may inadvertently be applied by the bus bar assembly; there is no one row of terminals which by itself would act to define a pivot point tending to permit rotation of the bus bar assembly about the row and thereby damage the card and the terminals; further the plurality of through-holes are now spaced farther apart than the same number would be spaced within a common row, allowing more card structure between the holes. Where the spacing of through-holes 184 cannot be positioned with absolute precision to correspond with the positioning of the terminals on a carrier strip, the compliant pin terminals may be separate from a carrier strip upon insertion.

The plurality of terminals extending from each flange to a respective through-hole region of the card edge define a plurality of distinct electrical connections therebetween dividing the current from the bus bar flange to a plurality of hole locations on the card, thus efficiently distributing the current to a substantial plurality of sites without exceeding the nominal capacity of individual terminals, and similarly efficiently gathering the return current. The carrier strips common the terminals after their receipt of the current by the first terminal sections of the row of terminals of the source bus bar (or by receipt from the second terminal sections of the return bus bar), and redistribute it to the second (or

first) terminal sections, thus compensating for a single less-than-optimum electrical connection at one of the first or the second compliant sections of one of the terminals of a row. Distribution of Joule or resistive heating from the terminal/board interface is also assisted by the carrier strip conducting heat from individual terminals.

The card can be customized to transmit the current received by each through-hole to an embedded power plane which may intersect all through-holes of the region and then conduct the current elsewhere on the board to components such as representative integrated circuit devices 192 in Figure 8. The compliant pin terminals and the mounting method disclosed accommodates different board thicknesses of from about 0.085 to 0.250 inches or more and is also forgiving of manufacturing tolerances in card thickness. Such essential independence from board thickness permits existing card cage systems having the power distribution of the present invention, to be upgraded without modification with new card modules having the bus bar assembly of the present invention, but having daughter cards of different thicknesses than the ones they replace.

The card may also utilize elevated bus bars of the type disclosed in U. S. Patent No. 4,869,673 which will extend from the card edge to the interior regions of the card's major surfaces thus essentially freeing up the major surface for use by signal circuits and components only, and simplifying card fabrication by eliminating the need for multilayered construction for embedding power circuitry within the card. Appropriate electrical connections can be provided from the through-holes to contact sections of the elevated bus bars near the card edge by surface or embedded card circuitry; it is also possible to utilize compliant pin terminals to interconnect the bus bar flanges directly to tabs on the elevated bus bars, with other mounting means such as bolts provided to affix the bus bar assembly to the card edge.

Bus bars 116,118 can be extruded for example of low resistance copper alloy such as Alloy No. C110 and then flanges 150,154 formed from an initially continuous flange portion to define recesses 152,156; blade-shaped contact section 122,124 can then be formed, then annealed to half hard temper and thereafter plated with nickel underplating and then silver plating followed by application of a tarnish resistant coating. It may be desirable to extrude both bus bars from adjacent portions of the same copper alloy extrusion to best assure an identical thickness, which may be about 0.187 inches. Pin-receiving apertures 166 of appropriate diameter such as 0.040 inches can be machined into flanges 150,154; the spacing between apertures of a single row may be 0.100

inches, and the rows may be spaced 0.065 inches apart; the through-holes of daughter card 102 would be identically spaced within each region and have identical diameters of 0.040 inches after plating.

Compliant pin terminals 174 can be stamped from a continuous strip of stock copper alloy such as Alloy No. C260 and having generally a rectangular cross-section of 0.025 by 0.034 inches, but with the diagonal across each compliant section 170,180 of about 0.050 inches to assure the desired substantial gripping force upon being reduced during insertion into flange apertures 166 and through-holes 184 respectively from 0.050 to 0.040 inches. Insulator 120 may be extruded for example from a thermoplastic such as nylon and have a shape conforming snugly to the outer shape of the bus bars affixed together and also include a flange-covering section 194 as well as rail 126, with polarizing rail flange portions 128 easily extruded. Insulator 120 may be inserted over the bus bar assembly before mounting to the card edge to facilitate handling of the bus bar assembly as a unit during card mounting, and then secured. Insulating layer 158 may be for example 0.005 inch double sided tape such as of MYLAR polyester or KAPTON polyimide.

The components of receptacle contact assembly 40 (or 42) are shown in Figures 12 and 13. Each receptacle contact member 44 (or 46) includes a body section 62 having a hole 82 therethrough within which is secured an insulative bushing 60. A shaft-receiving hole 84 is formed through bushing 60 through which extends shaft 64. Clevis block 66 includes a plurality of salients 86 spaced therealong through each of which is a shaft-receiving aperture 88, and contact-receiving recesses 90 are defined between salients 86 and having controlled widths greater than the width of body sections 62 of contact members 44. Shaft 66 may be retained in the assembly by a pair of locking clips inserted on end sections extending from the clevis block and having annular recesses therearound; clevis block 66 preferably has mounting flanges 92 for being mounted to the card cage framework.

Each receptacle contact is preferably stamped from low resistance stock alloy such as Alloy No. C151 having a thickness of 0.062 inches for example, and then formed to have arrays of spring arms 52 in both forward and rearward receptacle sections 48,54, each spring arm having an angled free end. The contact is then formed so that body section 62 is rectangular in cross-section and so that the spring arms of each contact section oppose each other a precise selected distance apart of for example about 0.120 inches at blade-engaging arcuate constrictions at the bases of now-diverging opposed angled free ends together now

acting as a lead-in and defining a capture region for receipt of a slightly misaligned blade front end during mating. Since the forming of body section 62 involves abutting the free ends of the blank along a seam, the free ends must be locked together by a locking system such as the dovetail arrangement 78 wherein a tab is locked into an undercut groove similar to that disclosed in U. S. Patent No. 4,932,906; the locking system assures that all opposed spring arms sustain equivalent and appropriate contact normal force upon deflection during mating with a corresponding blade. The entire contact member may be plated with nickel underplating and silver plating as desired for terminals conducting substantial current levels. Receptacle contact sections 48 and 54 are preferred to be similar to that disclosed in U. S. Patent No. 4,845,589. Clevis block 66 may be molded for example of thermoplastic such as acetal resin, and shaft 64 may be a steel rod; insulative bushings 60 may be molded of thermoplastic such as nylon.

Receptacle contact assembly 42 is shown fully assembled in Figure 13, in association with power bus assembly 38. Power bus assembly 38 includes source bus member 68 and return bus member 58 having insulation 70 therebetween. Contact members 72,76 may be formed from low resistance copper alloy like Alloy No. C110 about 0.187 inches thick, annealed to half hard temper if desired, and nickel underplated and silver plated and followed by application of a tarnish resistant coating. Contact members 72,76 are mounted to respective ones of bus members 58,68 so that blade-shaped contact sections 56,74 respectively alternate with each other opposed from respective rearward receptacle contact sections 54 of receptacle contact members 44,46 of assembly 42. Power bus members 58,68 may be extrusions of copper alloy such as Alloy C110 with flange-receiving recesses and mounting apertures formed therein in order to be secured such as by conventional hardware to an insulative support 94 such as of thermoplastic acetal or glass-filled polyester resin in order to be mounted to the framework of the card cage. Insulation 70 may be 0.03 inch thick glass-filled epoxy. Receptacle contact assembly 42 is also mounted to the card cage framework forwardly of the associated power bus assembly, with rearward contact sections 54 mated with appropriate associated ones of blade-shaped contact sections 56,74 under substantial contact normal force such as about four pounds per spring arm.

The incremental aligning capabilities of the mating of the bus bar assemblies 110,114 of card module 100 with the separable interface defined by receptacle contact assemblies 40,42 and also the critical after-mating adjustability thereof, will now be described with reference to Figures 14 to 17,

and with reference to Figures 4 to 6. Figures 14 to 17 illustrate diagrammatically in plan view an upper bus bar assembly 110 of card module 100 approaching an upper contact assembly 40 mated with upper power bus assembly 36 of card cage 10, with a backplane connector 16 opposed from a corresponding card cage connector 106 on rear edge 104 of card 102 of card module 100; one of the several alignment posts 80 of backplane connector 16 is opposed from a corresponding post-receiving aperture 196 in card edge connector 106.

In Figure 14 a lower guide member 24 of cage framework 12 is visible forwardly of backplane 14 and has a guide channel 20 approximately aligned with backplane connector 16 and alignment post 80 thereof. First blade-shaped contact section 122 of return bus bar 116 is opposing and is approximately aligned with a corresponding receptacle contact member 44, while second blade-shaped contact section 124 of source bus bar 118 is opposing and is approximately aligned with a corresponding receptacle contact member 46; the forward receptacle contact sections 48,50 thereof extend forward of backplane 14 above an upper edge thereof.

Receptacle contact members 44,46 are mounted to clevis block 66 on shaft 64 thereof. Recesses 90 between salients 86 of clevis block 66 are slightly larger than the width of body sections 62 of members 44,46 permitting limited side-to-side movement and angular movement therebetween. Insulative bushings 60 through body sections 62 (Figure 12) have shaft-receiving holes 84 with inside diameters slightly larger than the outer diameter of shaft 64, thereby permitting limited angular or skewing movement of each receptacle contact member as well as rotational movement about the shaft, all generally pivotable about the gripping engagement of rearward receptacle contact sections 54 onto blade-shaped contact sections 56,74 of power bus contact members 72,76. Thus receptacle contact assembly can be said to define a floating separable power interface while still firmly mechanically and electrically connected to contact members of the power bus assembly of the card cage, with forward receptacle contact sections possessing limited movement capability in any direction in a plane parallel to the backplane.

In Figure 15 the front end of first blade-shaped contact section 122 has entered the lead-in of receptacle contact section 48 and has deflected apart the opposing spring arms 52 thereof, overcoming a peak insertion resistance of about eight pounds, while easily incrementally adjusting the position of the forward end of receptacle contact section 48 if necessary. Second blade-shaped contact section 124 is approaching receptacle contact section 50; card edge connector 106 is approach-

ing backplane connector 16.

In Figure 16 the front end of second blade-shaped contact section 124 has entered the lead-in of receptacle contact section 50 and has deflected apart the opposing spring arms 52 thereof, overcoming a peak insertion resistance of about eight pounds while easily incrementally adjusting the position of the forward end of receptacle contact section 50 if necessary, simultaneous with first blade-shaped contact section 122 being urged farther into receptacle contact section 48 against a friction resistance of about four pounds. Card edge connector 106 has been moved adjacent backplane connector 16, with the leading end 96 of alignment post 80 about to enter post-receiving aperture 196 at the entrance 198 defined by a chamfered lead-in.

In Figure 17 leading end 96 of alignment post 80 has engaged the lead-in surfaces of aperture entrance 198 and has urged the card edge connector incrementally at least laterally (and commonly vertically as well), necessarily also urging the entire rear edge 104 of card module 100 simultaneously, as well as the bus bar assemblies 110,114. During the incremental adjustment movement, the blade-shaped contact sections 122,124 of both bus bar assemblies also must necessarily move; the floating separable interface defined by receptacle contact assemblies 40,42 are adapted to permit such movement of already-mated blades and receptacles with acceptably low mechanical resistance over and above simple inertia.

Therefore, incremental adjustment of the rear card edge 104 in the horizontal direction is accomplished without having to overcome the stiff spring arms of one side of each of the four receptacle contact sections 48,50 mated with the four blade-shaped bus contact sections 122,124. The aggregate mechanical resistance by the arrays of spring arms of the four receptacle contacts would have been up to about four pounds per mil for horizontal movement. With the present invention this stiffness (plus friction from blade/finger wiping during incremental pivoting) is reduced to about 0.01 pounds per mil. For example, where horizontal adjustment movement might require a horizontal translation of twenty mils, the total mechanical resistance would have been eighty pounds, whereas such horizontal translation in the present embodiment of the present invention would encounter a total mechanical resistance of about 0.20 pounds, plus a certain additional resistance due to friction as portions of the insulative bushings may bear somewhat against portions of the smaller-diameter shaft in the clevis block.

Adjustment movement is accomplished in the vertical direction without having to overcome the full friction resistance of the spring arms gripping

the blades in order to move the blades relative to the spring arms. The aggregate friction resistance would have been up to about sixteen pounds for vertical movement; with the present embodiment of the present invention this aggregate friction resistance is reduced to about three pounds. Overcoming the deflection resistance of the spring arms and the friction resistance of the spring arms with respect to the blades would otherwise be necessitated were the receptacle contact members to be fixed mounted, and would have prohibitively stressed the precision alignment mechanism of the backplane and card edge connectors.

The power distribution system of the present invention permits powering of a daughter card module as a result of card insertion, where the power is brought to the side edges rather than the rear edge, thus freeing up all rear edge locations for signal connections with the backplane. Higher levels of power can be transmitted to the card than with commercially available systems. The system of the present invention distributes 75 amperes along one edge of the daughter card through 92 equi-current compliant pins with less than about 10 millivolts total voltage drop from the system bus to the most blade-remote daughter card site adjacent to the card edge bus. Return current is collected by the proximate bus with similar performance. Identical capability is provided by the card edge bus system affixed to the opposite edge of the daughter card. Where only one bus bar assembly is desired, an electrically inert or dummy rail member is applied to the opposite side edge in lieu of a bus bar assembly thereat.

The bus bar assembly of the present invention provides a pair of somewhat thin bus members opposing each other along facing major surfaces separated by a thin layer of insulation and providing a low impedance advantage along the daughter card edge. The thin nature of the bus members in the direction of the card array presents a relatively low profile module which permits forced air flow between adjacent cards from above and below the array. While the bus bars could be mounted to the card edge by conventional means such as bolts, the array of compliant pin terminals disclosed provide excellent mechanical mounting as well as excellent electrical connections at a substantial plurality of separate but closely spaced sites.

In the present invention, the bus assembly with its plurality of compliant pin terminals is assuredly but easily mounted to a card edge, and thus to real estate of the daughter card previously electrically unused. By compliant pin terminals entering the daughter card from a common side (the reference surface), the bus bars and the bus bar module are therefore essentially independent of substantial variations in card thickness. Since the card edge

connectors along the rear edge are also mounted with respect to the same reference surface, and the rail of the insulator is positioned with respect to the reference surface, consequently the card cage adapted for the power distribution system of the present invention is also essentially independent of such card thickness variations, and can be standardized.

The sequence of power first, signal last is achieved without interfering with precision alignability of the signal connectors on the rear edge with the backplane connectors while the card is under power, and the return power circuit engages before the source power circuit. Precision alignability is attained by reason of float mounted power contacts of the card cage bussing system at each card location. The present invention results in only minimal voltage drop from the card cage bussing system to the card's power circuitry.

Claims

1. A system for distributing electrical power to daughter cards (102) of a card cage (10), the card cage having a framework (12), a backplane (14), and a card-receiving region forwardly of the backplane (14), and means for bussing power to card locations in the card cage (10), and each daughter card (102) having power contact means matable with power contact means of said card cage connected to said bussing means upon full insertion of the daughter card into the card cage along guide means (22,24) at a card location, characterised in that:

said power contact means (122,124) of said daughter card (102) are defined at inner ends of bus members (116,118) mounted to at least an upper or lower edge (108,112) of the daughter card (102) and near inner edge (104);

said bus members (116,118) are electrically connected to a plurality of electrical circuits of said daughter card (102);

said contact means (44,46) of said bussing means (36,38) are mounted in alignment with and are matable with said power contact means (122,124) of a corresponding said daughter card (102) upon card insertion; and

said contact means (44,46) of said bussing means (36,38) are mounted in said card cage (10) in a manner permitting incremental positional self-adjustment at least upon initial engagement by a respective said bus member contact means (122,124).

2. A system as set forth in claim 1 further characterised in that each said bus member (116,118) includes at least one flange section

(150,154) adapted to extend a selected distance inward along a major surface of a said card (102) from a said one of said upper and lower edges (108,112) thereof to extend over power circuit means of said card (102), said card includes an array of through-holes (184) intersecting said power circuit means, and each of said flange sections (150,154) of each said bus member (116,118) includes a corresponding array of pin terminals (174) extending normally therefrom toward said array of through-holes (184), whereby said pin terminals (174) are received into respective said through-holes (184) to establish a plurality of electrical connections with said card power circuit means upon mounting of said bus members (116,118) to said card (102).

3. A system as set forth in claim 1 further characterised in that a pair of source and return bus members (116,118) are secured together as an assembly (110,114) prior to mounting to said card (102) and are insulated from each other.

4. A system as set forth in claim 3 further characterised in that each said bus member (116,118) includes a plurality of flange sections (150,154) of selected length alternating with flange-receiving recesses (152,156) of lengths just larger than said selected length, and said flange sections (150,154) of one said bus member (116,118) are offset with said flange sections (154,150) of the other said bus member (118,116) to correspond with said flange-receiving recesses (152,156) of said one bus member (116,118), whereby said bus members are securable together with said respective flange sections becoming interspaced between said flange sections of each other and nonengaging therewith.

5. A system as set forth in any of claims 3 or 4 further characterised in that said bus member assembly (110,114) includes an insulative covering (120) over portions extending away from said daughter card (102) in a manner exposing said contact members (122,124) for mating with said contact means (44,46) of said bussing means (36,38).

6. A system as set forth in claim 5 further characterised in that said insulative covering (120) includes a rail (126) corresponding with a complementary guide channel (18,20) of a guide means (22,24) of said card cage (10).

7. A system as set forth in any of claims 1 to 6 further characterised in that said contact mem-

bers (122,124) of said of said bus members (116,118) are blade-shaped, said corresponding contact means (44,46) include receptacle contact sections (48,50) facing outwardly and having lead-in forward ends adapted to receive 5
thereinto and thus mate with said blade-shaped contact sections (122,124), and said blade-shaped contact section (122) of each return one (116) of said bus members extends 10
farther inwardly than said blade-shaped contact section (124) of each source one (118) of said bus members to mate first and unmate last.

8. A system as set forth in any of claims 1 to 7 15
further characterised in that each said contact means (44,46) of said bussing means (36,38) is secured to said card cage framework (12) and connected to said card cage bussing means (36,38) in a manner permitting incremental adjustment movement thereof in a direction transverse to the card insertion direction at least after mating with a respective said contact section (122,124) of a said bus member (116,118), permitting positional adjustment of said inner card edge (104) with respect to 20
connectors (16) of said backplane (14) just prior to mating of said inner edge connectors (106) with said backplane connectors (16).
9. A system as set forth in claim 8 further characterised in that said contact means (44,46) of 30
said bussing means (36,38) are receptacle members mounted to a clevis block (66) of said framework (12) and each includes a receptacle contact section (48,50) facing forwardly and adapted to receive therein to a respective blade-shaped contact section (122,124) of a card bus member (116,118) defined by an array of paired opposed spring arms (52) extending forwardly from a body section (62) 35
pivotably and somewhat loosely mounted along a shaft (64) of said clevis block (66) in a manner permitting incremental movement during and after mating with a corresponding said blade-shaped contact section (122,124). 40
45
10. A system as set forth in claim 9 further characterised in that said receptacle members (44,46) are mounted at locations vertically offset from backplane connectors (16) matable 50
with connectors (106) mounted along said inner edges (104) of said daughter cards (102), and said blade-shaped contact members (122,124) are correspondingly vertically offset from said card edge connectors (106). 55
